COCO 3 SECRETS
REVEALED

from microcom software

licensed by spectrum projects
COCO III SECRETS REVEALED is a filled with useful information and powerful secrets that will help you utilize the new features of your Color Computer III. It will present several unique routines and show you some powerful features that were not available with the Color computer or Color Computer II.

COCO III SECRETS REVEALED does not require any knowledge of machine language. It should be noted that this book was written to explain the features of the new Coco III and since some of the new features are of a technical nature, there will be sections of this book that may not be fully understood by everyone.

COCO III SUMMARY.........................................PAGE 37
The Color Computer has been around for quite a while in one form or another. The first version was known as the "C" board. Most people never heard of this version; there were only a few hundred produced and it was quickly upgraded to what is normally thought of as the first Color Computer, the "D" board.

This computer came with either 4 or 16K of memory, with Standard or Extended basic. It wasn't long before 16K of memory just wasn't enough, so someone figured out a way to install up to 32K of memory. Radio Shack followed suit and came out with the "E" board which was able to use 32K of memory without performing major surgery on the computer. As games became more complex, more memory was required so somebody discovered a way to increase the Coco's memory to 64K. Radio Shack again followed suit and produced the "F" board. In the years that followed the computer technology grew tremendously and a cost reduced version of the Color Computer appeared as the Color Computer II and Color Computer IIA.

During all of these changes, not once was anything done about improving the graphics capabilities. Oh sure, artifecting was discovered, tricky use of the interrupts was used to manipulate the screens in new ways, however these were not actual changes in the computer, but instead the work of some extremely clever and creative programmers.

It is again time for an upgrade, a few companies have already come out with memory upgrades to 128K, 256K and even 512K. In the spirit of keeping a tradition going, Radio Shack has again followed suit, but this time they have gone a step further by addressing some of the other limitations of the Color Computer.

The Color Computer III is Radio Shack's solution to these limitations. Listed below are some of the new and advanced features:

1. Three display interfaces are included, Standard TV, Composite monitor (monochrome or color) and Analog RGB.
2. Three character text modes are available, 32x16, 40x24 and 80x24.
3. True lower case is available in the 40 and 80 column modes however, basic still does not understand lower case commands.
4. Graphics resolution has increased to a maximum of 640x225.
5. Up to 16 colors can be displayed at a time and can be chosen from a palette of 84 different colors.
6. Memory starts at 128K and can be increased to 512K.
7. Smooth scrolling is available in both the horizontal and vertical directions.
8. True double speed is now supported.
9. There are now two fire buttons per joystick.
10. The IRQ and FIRQ interrupts are each divided into six separate sources. Programmable timer, horizontal border, vertical border, serial data, keyboard data and cartridge interrupts.
11. Along with all of these new features, the Coco III will still run about 90% of the current Color Computer
Almost anytime you add new features to something, you also create new problems to go along with them. This is true in the case of the Coco III also, listed below are a few of these. Most of the problems are minor ones but deserve to be mentioned.

1. Since artifacting is primarily a product of your video display, it is something that the computer cannot really correct. In the higher graphics modes, some detail in resolution is lost if you are using a TV or a composite monitor. If you are using an analog RGB monitor, the new graphics modes work very well however, the old modes which rely on artifacting to produce colors won’t work since RGB monitors don’t artifact.

2. In order to fit 40 and 80 column text on the screen, the screen area has been widened. This is great so far as the readability of the text is concerned, because the 40 column characters are exactly the same size as the 32 column characters, and the 80 column characters are a little bit larger than the old software driven 51 character screens. A problem occurs because when the screen was widened, it was also shifted slightly to the left. This has the annoying effect on some TV and Composite displays of shifting the first few characters off of the left side of the screen totally out of view. It may be possible to adjust this if your television or composite monitor has a horizontal hold control. THIS DOES NOT APPEAR TO EFFECT THE RGB MONITORS.

3. Smooth scrolling in the horizontal direction requires 48K of memory to allow proper wrap around. Neither the horizontal or vertical scrolling are supported by basic commands, Peek and Poke must be used.

4. Basic has not been re-written. The new commands have been patched into the old code. This point is both good and bad. On the good side, most of the existing software will work without modification, also since Basic is now always in RAM, it is very easy to add patches and modifications of your own. On the bad side, any short commencings that Basic originally had will still exist. For example, only 32K can be used for basic programs, the PCOPY bug still exists and PCLEAR O still is not allowed.

5. Because of the new interrupts, some multi-pak interfaces will require a small modification.

NOTE: A good monitor to purchase which will eliminate the Composite/RGB problems is the Magnavox 8505. It has a TTL (RGBI) input for IBM computers, an ANALOG RGB input for the Coco III and a COMPOSITE (Audio/Video) input which will allow artifacting games to show up in color. I have found three places that sell these monitors, TOYS R US for about $200.00 (without a cable), PRICE SAVERS WHOLESALE WAREHOUSES for about $170.00 (without a cable) and SPECTRUM PROJECTS for about $200.00 (with a cable).
New Basic commands have been added to the existing commands by Microware Systems Corp. These new commands allow access to some of the Coco III's new features. Following is a brief list:

<table>
<thead>
<tr>
<th>Command</th>
<th>Command</th>
<th>Command</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>HSCREEN</td>
<td>PALETTE</td>
<td>HCLS</td>
<td>HPOINT</td>
</tr>
<tr>
<td>HLINE</td>
<td>HCOLOR</td>
<td>HPaint</td>
<td>HDRAW</td>
</tr>
<tr>
<td>HSTAT</td>
<td>HBUFF</td>
<td>HSET</td>
<td>HRESET</td>
</tr>
<tr>
<td>HCIRCLE</td>
<td>HGET</td>
<td>HPUT</td>
<td>HPRINT</td>
</tr>
<tr>

<td>LPEEK</td>
<td>LPOKE</td>
<td>ONERR</td>
<td>ONBRK</td>
</tr>
<tr>
<td>ERLN</td>
<td>ERNO</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

These commands will be listed in a later chapter along with a brief explanation of what each one does. Most of them are high resolution counterparts of already existing commands with syntaxes that are the same or similar. The rest of them deal with error and break key control and commands for manipulating the new text screens. The bulk of this book will concentrate on the new hardware features of the Color Computer III. Short Basic programs which use some of the new commands will be used to help further your understanding of these features.
In order to get started, there are a few things we need to know about the way the Color Computer III does things. The Coco III, as we said earlier, is capable of using 512K of memory but the CPU, a 6809E, is an 8 bit microprocessor and can only directly address 64K of memory at a time. Because of this a special method known as MEMORY MANAGEMENT must be used. Memory management is a scheme which maps a block of memory into the CPU's 54K workspace when it is needed. In some systems this process is automatic, but in the Coco III this is not the case.

In the Color Computer III, the CPU's 64K bank or workspace is a separate entity than that of the memory. This 64K workspace is divided into eight 8K slots by the Memory Management Unit (MMU) and each slot is controlled by an MMU register. The actual memory used in these slots is determined by the values stored in the MMU registers. Basic initializes these registers to the highest part of the 512K memory space (even if you only have a 128K system). This is actually the address range of $70000 to $7FFFF but the CPU will see it as $00000 to $FFFF.

The MMU registers are located in memory at $FFAO-$FFAF, please note that there are 16 registers but only 8 of them are needed to define the CPU's 64K workspace. This is because there are actually two sets of MMU registers. By using both sets you can map the CPU's 64K workspace two different ways and quickly toggle between the two set ups by using the task register (TR). The TR is located at bit 0 of the control register at $FF91.

The following table shows each MMU register address and the specific block of CPU workspace that it controls:

<table>
<thead>
<tr>
<th>TR</th>
<th>MMU REGISTER</th>
<th>BK BLOCK</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<tr>
<td>1</td>
<td>$FFAF</td>
<td>$E000-$FFF</td>
</tr>
</tbody>
</table>

The Color Computer III's memory is also divided into 8K blocks. There are a total of 64 8K blocks of memory (0-$3F) and each one is referenced by a number. The first 8K block is block 0, the second is block 1 and so on. If you only have a 128K system then blocks 0-$5F, $10-$1F and $20-$2F will be mirrors of blocks $30-$3F, in other words if you only have 128K and you try to place
block 0, block $10 or block $20 into the CPU's memory space, block $30 will appear to be there instead. So in a 512K system you have memory blocks 0-$3F available for mapping into the CPU's workspace, but in a 128K system you only have blocks $30-$3F available.

Moving a block of memory into the CPU's workspace is done by simply placing the number of the block that you want into the CPU workspace slot of your choice. It is possible to put the same block of memory into more than one CPU memory slot. It is important to note that placing a new block of memory into one of the CPU's workspace slots, does not affect the information of the block that was in that slot previously. For example, if the CPU workspace slot controlled by the MMU register at $FFAO currently contains a $38, and we replace it with block $39, the information stored in block $38 does not get hurt or destroyed in any way, it is simply moved out of the CPU's workspace and can be brought back at any time by storing a $38 into one of the CPU's memory slots (it could be the one at $FFAO, but it doesn't have to be). In a later chapter we will manipulate the MMU registers to allow a 32K graphics screen to be saved from basic.

PALETTE REGISTERS are another item that need a little explanation. On the old Color Computer, colors were generated on the graphics screen by placing the proper bit pattern on the screen for the color you wanted. The Color Computer III does this in nearly the same way, a bit pattern is still placed on the screen, but instead of this pattern defining the color, it points to a palette register. The value that is stored in the palette register is what actually defines the color. There are 16 palette registers available but the number of active ones is determined by the graphics color mode selected. In the 16 color modes all 16 registers are active, in the 4 color modes only 4 registers are active and in the 2 color modes just 2 registers are active. Regardless of the color mode, the active palette registers may be set to display any of the 64 different colors simply by storing the code for that color into the proper register. It is possible to store the same color into any or all of the active palette registers. Following is a list of the 64 available colors and their codes. Please note that the codes do not necessarily generate the same colors on a composite monitor as they do on an RGB monitor.
The following short program called RGBTOCMP is an example of how the above palette information can be used to make your programs more useful on both RGB and Composite monitors. The data for composite colors are read into the array CP in RGB color order. Line 30 selects palette register 8 and an RGB color of 16 (medium green). The subroutine at line 900 will determine which type of monitor is being used and set the selected palette register to the proper value.

5  RGB=1 'Set to 0 if composite monitor used
10  DIM CP(63) 'Set up array for composite values
20  FOR X=0 TO 63:READ CP(X):NEXTX 'Fill array
30  PL=8:CL=16 'Palette to change (PL) RGB value (CL)
40  GOSUB 900 'Call conversion routine
50  GOTO 50
900  IF RGB=1 THEN PALETTE PL,CL:RETURN
910  PALETTE PL,CP(CL) 'Use array value if Composite
920  RETURN
1000 DATA 0,12,2,14,7,9,5,16,28,44,13,29,11,27,10,43
1010 DATA 34,17,18,33,3,1,19,50,30,45,31,46,15,60,47,61
1020 DATA 23,6,21,6,39,24,38,54,25,42,26,58,24,41,40,56
1030 DATA 20,4,35,51,37,53,36,52,32,59,49,62,55,57,63,48
To help make use of the Color Computer III's enhanced features, a set of new commands has been added. Basically the commands deal in 3 areas, graphics, character display and miscellaneous enhancements. Each new command, along with a brief description of the function it performs, will be discussed in this chapter. The commands will be broken into the three groups listed above and presented in that order. It should be pointed out that this list of commands was included simply for reference while examining the programs in this book and is not intended as a programming aid. The manual which was included with your Coco III was designed, and is better suited for this purpose.

GRAPHICS:

PALETTE R,C - Places the color code indicated by "C" into the palette register indicated by "R". The command PALETTE 15,63 would place the color code for white into palette register 15. Instead of "R" and "C", the words CMP or RGB may be used to set up system defaults for composite (CMP) or RGB monitors.

HSSCREEN M - Activates and displays the graphics mode selected by "M". 0 = text mode, 1 = the 320x192 4 color mode, 2 = the 320x192 16 color mode, 3 = the 640x192 2 color mode, 4 = the 640x192 4 color mode.

HCLS R - Clears the graphics screen to the palette specified by "R". The actual color of the screen will be determined by the color code stored in that palette register.

HCOLOR F,B - Sets the Foreground and Background defaults to the palettes specified by "F" and "B". The palettes specified will be used as defaults during certain graphics commands such as line and circle if no palettes are specified.

HSET (X,Y,R) - Sets the point at horizontal coordinate X, vertical coordinate Y to the palette specified by "R". If "R" is omitted, the foreground palette specified by the HCOLOR command will be used.

HRESET (X,Y,R) - Sets the point at horizontal coordinate X, vertical coordinate Y to the palette specified by "R". If "R" is omitted, the background palette specified by the HCOLOR command will be used.

HPOINT (X,Y) - Returns the palette value located at the horizontal coordinate X and vertical coordinate Y. HPOINT is considered a function because it returns a result to Basic rather than performing an action. The proper syntax for this command is A=HPOINT(X,Y) where "A" is the variable that will contain the result and "X" and "Y" are the horizontal and vertical coordinates.

HLINE - Draws a line from X1,Y1 to X2,Y2. The syntax for this command is the same as the LINE command of Extended Basic.
HDRAW - Allows you to draw a shape by giving an imaginary graphics cursor direction and color instructions. The syntax for this command is the same as the DRAW command of Extended Basic.

HCIRCLE - Allows a circle to be drawn on the screen. The syntax for this command is the same as the CIRCLE command of Extended Basic.

HPAINT - Allows an area on the screen to be filled with a palette. The syntax for this command is the same as the PAINT command of Extended Basic.

HPRINT (X,Y),"STRING" - Allows text messages to be displayed on the graphics screen. X and Y are the horizontal and vertical coordinates at which to start. "STRING" is the message to be printed, up to 40 characters (80 for HSCREEN 4) may be displayed on a line. The character color and the color of it's background is determined by the foreground and background colors set with the HCOLOR command.

HBUFF N,A - Reserves a memory buffer for HGET and HPUT where "A" is the number of bytes to reserve and "N" is the buffer number. This method is used instead of dimensioning an array to reserve space (Buffer is limited to 8K).

HGET - Gets an area of screen memory and places it in the buffer specified. The syntax for this command is the same as the GET command of Extended Basic.

HPUT - Takes the screen memory that was saved by HGET and puts it onto the screen at the coordinates specified. The syntax for this command is the same as the PUT command of Extended Basic.

CHARACTER DISPLAY:

WIDTH W - Changes the character width of the display to the value specified by "W". Legal values are 32, 40 and 80.

LOCATE X,Y - This command is used instead of the PRINT@ statement of Basic for the 40 and 80 column screens. The cursor will be positioned at the horizontal and vertical coordinates specified by "X" and "Y".

HSTAT A$,A,X,Y - Returns the X/Y position, the attributes and the character located at the current cursor position.

ATTR F,C,B,U - Sets the attributes of the character located at the current cursor position. Foreground color, Background color, Blink and Underline options may be specified.

MISCELLANEOUS ENHANCEMENTS:

BUTTON - Returns the status of the specified joystick button. The command A=BUTTON(0) will return the status of button 0. 0=Right button 1, 1=Right button 2, 2=Left button 1, 3=Left button 2.
ONERR - Allows the user to trap system errors. The command ONERR GOTO 100 would transfer program control to line 100 anytime a system error occurs.

ERNO - Contains the number of the system error that just occurred.

ERLN - Contains the line number where the last system error occurred.

ONBRK - Allows the user to trap the break key. ONBRK GOTO 1000 would transfer control to line 1000 when the BREAK key is pressed.

LPEEK - Allows peek access into the entire 512K memory range.

LPOKE - Allows poke access into the entire 512K memory range.

Modifying old programs to work with the new graphics and text features if the Color Computer III is NOT a very difficult job. In the case of most graphics commands, it is just a matter of adding an "H" in front of the old command. PAINT becomes HPAINT, DRAW becomes HDRAW, CIRCLE becomes HCIRCLE and so on. In some cases other changes must also be made, for example PRINT will not work on the 40 or 80 column screens, LOCATE must be used instead, another example would be when using HGET and HPUT, instead of dimensioning an array to hold the graphics information, HBUFF must now be used to reserve this space.

The following program, CC2TOCC3.BAS, will aid in converting your old programs. It won't do everything, but it will handle the majority of the work and will flag out most of the problem areas by preceding the command in question with two asterisks. CC2TOCC3.BAS works with DISK ONLY, it reads in a normally saved basic file and writes out a converted ASCII file. Notice that the command LPEEK was included twice in the area for the new secondary functions, this is not a mistake. Due to a bug in basic, the new secondary functions skip token 168 and start with 169, the first LPEEK is simply a dummy to take this error into account.

CHAPTER 3
PLAYING WITH PALETTES

One of the nicest new features of the Color Computer III is the ability to display your choice of 64 different colors, 16 at a time on a high resolution screen.

On the Color Computer and Color Computer II, each pixel (picture element) was defined by two bits (1/4 of a byte). If we use two bits to count in binary, the most different combinations we can attain is 4 (00, 01, 10, 11). These bit pairs were hard wired to a specific color and the only time that a color could change was if they all changed by switching color modes.

In the Coco III 4 color mode, the description would be the same except that the colors are not hard wired anymore. Instead of the bit pairs defining a color, they point to a byte in the I/O space called a palette register. Each palette register may be programed individually with one of 64 different color codes. In the 2 color mode, two palette registers are used, in the 4 color mode, 4 of the palette registers are used and in the 16 color mode, all 16 of the palette registers are used. (The 2 color mode uses one bit per pixel, the four color mode uses 2 bits per pixel and the 16 color mode uses 4 bits per pixel).

The palette registers are located in memory from $FF80 to $FFBF and may be set by either POKEing new values or by using Basic's PALETTE command. The only way to read what is stored in a palette register is to use the PEEK command and AND the result with 63. PEEK($FFB1) AND 63 would read the value stored in palette register 1.

Any palette register may contain any color at anytime. If desired, all palette registers may be set to the same thing. Changing a palette register to a new color will cause all pixels pointing to that palette to instantly change to that color. The following Basic program called CIRCLES will draw 4 circles on the screen in different palettes and set them all to the same color. It will then wait for the keys "1", "2", "3" or "4" to be pressed, each key will turn on a different circle when pressed and turn it off when released. Notice in line 110 that the last statement is CMP. This is the same as the command PALETTE CMP. Also take a peek at lines 2 and 3 for some useful POKES.

58 POKE&HFFD8,0:cmp

The next example is a little more elaborate and involves a fairly long program. It will build a large ball onto the graphics screen and make it appear to rotate by simply changing the palette registers through a series of colors. To save space, and typing time, the DATA statements from lines 310 to 720 only contain the top left corner of the ball, the program will take this data and mirror it into a complete ball. The DATA statements from lines 240 to 290 contain the ball pattern information and may be changed to create different patterns on the ball. Notice that the last value of each line is an "F", this determines the palette used for the background area of the ball and should not change. Each of these values is the number of the palette register to use for that area of the ball.

All color displayed on the screen is controlled by the palette registers, this is true even for the text modes. In the Color Computer compatible mode's 32x16 screen format, the background screen color is controlled by palette 13 and the color of the text is controlled by palette 12. This is the only Coco III text screen where these registers are forced. In the 40 or 80 column screens the ATTR command may be used to point the text and individual character backgrounds to different palettes. In fact the 40 and 80 column screens are set up entirely different, instead of one byte per text character, the 40 and 80 column screens use two. All even numbered bytes contain the value of the character to display, and the odd bytes contain the attributes for that character. The attribute bit definitions are defined in chapter 5.

The 40 and 80 column screens are located in memory at address $6C000 and is only moved into the CPU's 64K workspace when a character needs to be printed. This nice because it means that the high resolution text screens do not use any of Basic's program space. The following routine will LPOKE all of the available characters onto the text screen.

WIDTH 40:LOCATE0,10
AT=16
FOR X=0 TO 510 STEP 2
LPOKE &H6C000+X,INT(X/2):LPOKE &H6C000+X+1,AT
NEXTX

The second portion of line 40 pokes in the attribute byte for the character preceding it, you can easily play around with this by changing the value of AT which is set in line 20.

It should be noted that the blink rate of a character that has the blink attribute bit set is controlled by the programmable timer interrupt ($FF94 and $FF95). If both of these bytes are zero'd, the characters will not blink.

The following program called "CC3WORD" will give you an example of how the 40 and 80 column text mode commands may be used to create some very powerful programs with almost no effort. "CC3WORD" is a simple single screen word processor, it allows you fill the screen with text, save it and print it (Press BREAK to get

Some new enhancements are also available for the 32X16 screen, these include true lower case, border color change and an invert screen color mode. Basic was not re-written to allow these
features to work, but since it now always resides in RAM, a simple POKE may be used to correct this problem.

POKE &H95C9, &H7F

This will prevent the console out vector from resetting the values at $FF22. To enable true lower case, POKE &HFF22, &H10. To enable the inverted screen mode, POKE &HFF22, &H20 and to enable the border color invert, POKE &HFF22, &H40. To get a combination of these features, add the values of the features desired together and POKE address $FF22 with the result.
CHAPTER 4
SMOOTH SCROLLING, PEEKS AND POKEs, AND OTHER TIDBITS

The most interesting new feature of the Color Computer III is its ability to smooth scroll in both the vertical and horizontal directions. Scrolling is not supported by Basic except through the use of the POKE command.

Vertical scrolling is controlled by three registers of the GIME (Graphics Interrupt Memory Enhancer) chip, $FF9D, $FF99 AND $FF9E. These registers work together to display addresses within the 512K system, in register $FF9C only bits 5-7 are used. Each time these registers are incremented, the display moves by 8 bytes. In order to scroll an entire row, the registers need to be incremented by a value which is equal to the NUMBER OF BYTES PER HORIZONTAL ROW divided by 8. The following example will start at Basic's graphics page ($60000) and scroll the screen according to the position of the joystick. The particular screen being viewed has 160 bytes per horizontal row.

10 ONBKR GOTO 190
20 HSCREEN 2:HCLS
30 HCIRCLE(160,96),40,4
40 HPAINT(160,96),5,4
50 ST=49152
60 J0=JOYSTK(0);J1=JOYSTK(1);J1=J1-32
70 IF INKEY$="Q"THENST=49152:GOSUB150:END
80 S=SGN(J1);J1=ABS(J1)
90 IF J1<15 THEN S=0
100 IF J1>23 THEN S=S*2
120 IF J1>30 THEN S=S*3
130 ST=ST-(S*(160/8)):GOSUB 150
140 GOTO60
150 A=INT(ST/65536):A0=A*32
170 POKE$FF9C,A0:POKE$FF9D,A1:POKE$FF9E,A2
180 RETURN
190 ST=49152:GOSUB150

Line 130 is where the registers get incremented, "$S" will equal -1, 0 or 1 depending upon the position of the joystick. This will be multiplied by the number of bytes per horizontal row (160) divided by 8. This value is then converted by the subroutine starting at line 150, into the 3 bytes necessary for storage into registers $FF9C, $FF9D and $FF9E. To make the scroll faster, add the DOUBLE SPEED poke to line 10 (POKE$HFF9D,0).

The horizontal scroll register is located at address $FF9F. Only 7 bits (0-6) of this register are used to control the scroll, bit 7 is used to activate the HORIZONTAL VIRTUAL ENABLE (HVEN) mode. Horizontal Virtual Enable uses 48K of memory, is not accessible through Basic except with pokeys and is required anytime horizontal scrolling needs to do a complete wrap around. HVEN works by forcing the bytes per horizontal row to 256, the graphics mode selected has no effect on this except to define how much of
the 256 horizontal bytes to display. In other words, if a 320X192 (160 bytes across) graphics mode is selected while HVEN is turned on, the screen will show the normal 160X192 bytes and an area of 96X192 bytes will be hidden off of the edge of the screen. The following diagram will help clarify this.

```
0 320 512
0
--- --- --- --- 256 bytes ---
--- --- --- ---
--- --- 160 bytes --- --- ---
--- --- --- ---

This is the area that is displayed on the screen.

--- --- --- --- --- --- ---

This area is hidden from view.
```

The following short program will set up a horizontal virtual enable screen, clear it with a small machine language routine (Basic will only clear a 32000 byte screen), LPOKE a colored block on the screen and allow it to scroll according to the position of the joystick.

NOTE: THIS PROGRAM MAY NOT FUNCTION ON EARLY RELEASES OF THE COCO III DUE TO A RAM TIMING PROBLEM. TANDY HAS CORRECTED THE PROBLEM BY USING RAMS WITH A FASTER ACCESS TIME. CONSULT YOUR DEALER IF YOU ARE HAVING PROBLEMS.

```
Line 50 pokes in a small machine language routine that will zero the 8K block of memory locate at $6000 of the CPU's workspace. Line 60 then swaps each 8k block of memory required for the graphics screen into the slot at $6000 and executes the routine to clear it. Notice that at line 160, the Horizontal Offset (HO) is OR'd with $80, this will insure that HVEN will remain set. If for some reason it was desirable to not be in the HVEN mode, HO would need to be ANDed with $7F to insure that the HVEN bit was forced off.

Along with the blessing of more memory comes the greater possibility that part of it may be bad, it's simply the law of averages and somewhere down the line the law will catch someone. The following routine is a simple 128/512K memory test program, written partially in Basic with a small machine language routine that will check the 8K block of memory located at $6000 of the CPU's workspace. The Basic program will be used to print messages, sequentially swap 8K blocks of memory into the slot at $6000 and execute the machine language routine to check the block.

The new high resolution screens are great. Very detailed pictures, graphs and charts can be drawn and painted with a variety of different colors. The 320X192 screen uses 32K bytes of memory. This memory is not taken from the Basic program area which means that your program size doesn't have to suffer when using the new high resolution screens. It also means (because of the screen size) that you can't directly save the screen to tape or disk. A Basic program must now be used to save the screen a block at a time. The number of blocks to save is determined by the size of the screen, remember, each block is 8K, so a 32K screen would use 4 blocks. Basic always puts it's graphic screen starting at block $30, so to save a 32K screen blocks $30, $31, $32 and $33 would all need to be saved. The following routine will illustrate how this is done.
5 WIDTH 40
10 CLEAR200,"H5FF" 'Reserves 8K from $6000 to $7FFF
15 ONERR GOTO 200
16 POKE&H6C6,18:POKE&H6C7,18 'disable clear screen
20 CLS:PRINT"(S)AVE OR (L)OAD A SCREEN?"
30 A$=INKEY$:IF NOT(A$="S" OR A$="L") THEN 30
40 IF A$="S" THEN AC$="SAVE":A=0 ELSE AC$="LOAD":A=1
50 PRINT"ENTER FILENAME TO "AC$":LINEINPUT FL$
60 IF FL$="" THEN END
65 C=INSTR(FL$,",")$:IF C=0 THEN C=INSTR(FL$,"/")
67 IF C<>0 THEN FL$=LEFT$(FL$,C-1)
69 HSCREEN2
70 FOR X=&H30 TO &H33:POKE&HFFA3,X
75 IF A=0 THEN SAVEFL$:"+STR$(X),&H6000,&H7FFF,&H6000
80 IF A=1 THEN LOADFL$:"+STR$(X)
90 NEXT X:PRINT AC$;" SUCCESSFUL":END
200 OPEN"0",0,""
210 PRINT:PRINT "ERROR ENCOUNTERED DURING ";AC$:END

Notice the OPEN statement in line 200, it opens a file to the screen. This may seem like a strange thing to do, but it is necessary in this case because the routine that handles the ONBRK control does not reset the device number to the screen. Most of the time this will not effect anything, but here the error could ocured while accessing the disk which would cause the message in line 210 to be printed to the disk buffer instead of to the screen. Other commands that will reset the device number are CLS and POKE&H6F,0.

PEEK and POKE are a couple of commands that allow direct access to memory within the CPU's 64K workspace. Some very powerful things can be accomplished if they are used properly, to include modifying Basic. Listed below are a few interesting and useful changes that can be made.

To prevent HSCREEN command from clearing the screen:

POKE&H6C6,18:POKE&H6C7,18

To change the rate of blink rate of characters with the blink attribute set:

POKE&HFF94,(MSB OF BLINK RATE)
POKE&HFF95,(LSB OF BLINK RATE)

To change the color values for the CMP command, poke a value from 0 to 63 into the memory between $E654 - $E683. ($E654=PALETTE 0, $E655=PALETTE 1, ETC.)

To change the color values for the RGB command, poke a value from 0 to 63 into the memory between $E664 - $E673. ($E664=PALETTE 0, $E665=PALETTE 1, ETC.)
To fix a bug and make the CMP and RGB commands change all 16 palette registers:

POKE&HE648,16

To change the depth of the HSCREEN graphics modes from 192 to 200 and to allow the graphics commands to reach down that far:

POKE&HE06C,&H35
POKE&HE06D,&H3E
POKE&HE06E,&H34
POKE&HE06F,&H3D
POKE&HEB75,199
POKE&HE78A,200
POKE&HE78B,199
POKE&HEF8F,18

To change the cursor on the Width40 and Width80 screens:

POKE&HF797,X
POKE&HF7A3,X
POKE&HF7EC,X
POKE&HF80F,X
POKE&HF84F,X
POKE&HF918,X
POKE&HF89C,X

(Where X equals the attribute value to use. See character attributes in chapter 5 for more information.)

To find out the current screen width:

PRINT PEEK(&HE7)
(0=32 Characters, 1=40 Characters, 2=80 characters)

To find out the current HSCREEN mode:

PRINT PEEK(&HE6)
(0=TEXT, 1=HSCREEN 1, 2=HSCREEN 2, 3=HSCREEN 3, 4=HSCREEN 4)

To find the current default foreground color for HSCREEN graphics modes:

PRINT PEEK(&HFED0)

To find the current default background color for HSCREEN graphics modes:

PRINT PEEK(&HFED8)

To find the current ON BRK line number:

PRINT PEEK(&HFEDC)*256+PEEK(&HFEDD)
To find the current ON ERR line number:

PRINT PEEK(&HFEDE)*256+PEEK(&HFEDF)

High resolution character set for HPRINT is located between:

&HF09D - &HF39C

The characters are arranged in the following order:

NUMBERS AND SYMBOLS
(space)!"#$%&'()*+,-./0123456789:;<=>?

UPPER CASE CHARACTERS
@ABCDEFGHIJKLMNOPQRSTUVWXYZ (backslash) [(up arrow)(left arrow)

LOWER CASE CHARACTERS
{abcdefghijklmnopqrstuvwxyz (vertical bar)%(tilde)

Each character requires 8 bytes to describe it. The first byte defines the top row of the character, the second byte defines the second row, the third byte defines the third row and so on. There are a total of 96 characters and each character begins on an 8 byte boundary starting from address $F09D. The following table shows the 8 bytes required to build the upper case A. Each 0 within the byte is shown as a "." and each one is shown as a "*", this was done primarily to make the appearance of the character stand out.

<table>
<thead>

</tr>
<tr>
<td>$00</td>
<td>.............</td>
</tr>
</tbody>
</table>

A new character may be formed by changing the bit patterns for each of the 8 rows and POKEing the bytes into their proper place in the table. Once your character set is complete, you can use the CSAVEM or SAVEM command to save it to your cassette or disk for later use. Remember, these characters are only used during HPRINT, and will not effect the characters on the WIDTH40 or WIDTH80 text screens. The following Basic program called CHAREDIT can be used to edit the character set that is in memory and allows you to save it onto the disk. For use with a cassette, change the LOADM and SAVEM in line 960 to CLOADM and CSAVEM.

The program starts up by asking you for an initial file to load. This file will become the base file used during the recover command. If you do not load a file at this time, then the font currently in memory will be used. Following is a list of command keys and their functions:

<F1> Selects the previous character for edit.
<F2> Selects the next character for edit.
<Shift F1> Selects the 10th (previous) character for edit.
<Shift F2> Selects the 10th (next) character for edit.
<1> Selects the first character for edit.
<=> Selects the last character for edit.
<P> Selects character for edit by position.
<V> Views the current edited character.
<Clear> Erase current character.
<R> Restores original character.
<S> Saves character set to disk.
<L> Loads character set from disk.
<Lft arrow> Moves edit cursor to the left.
<Rgt arrow> Moves edit cursor to the right.
<Up arrow> Moves edit cursor up.
<Dwn arrow> Moves edit cursor down.
<Spacebar> Sets/resets point at edit cursor.
<Q> Quit program
<Break> Quit program.

Font files saved by this program may be loaded into memory at any time by using the LOADM command. This will allow for special fonts to be made and used from your Basic programs. It should be noted that you need not create just normal characters; special shapes, lines or anything else you might dream up may be created and used to achieve special effects. The NORMAL CHARACTER shown on the right side of the screen is the character to HPRINT from basic in order to display the new font character you have created.
CHAPTER 5
COCO III MEMORY MAP

The Color Computer III has two modes, the COCO mode which acts just like a Color Computer or Color Computer II, and an ADVANCED VIDEO PROCESSOR (AVP) mode which uses memory management, new high resolution screens and the other new features of the Color Computer III. In brief, the memory map looks something like this.

Total range: 0000 - $7FFFF (512 Kilobytes)

I/O and Control: XFF00 - XFFFF (All banks)

ROM: $78000 - $7FEFF (Deselectable) 
or $78000 - $7FDFF (Deselectable)

RAM:

64K Coco mode: X0000 - XFEFF (Except for ROM)

128K Coco mode: X0000 - XFEFF (Except for ROM)  
4 additional 16K pages at X4000 - X7FFF

128K AVP mode: $80000 - $7FEFF (Except ROM, I/O & CTRL)  
Duplicated at... $40000 - $5FFFF  
$20000 - $3FFFF  
$00000 - $1FFFF

512K Coco mode: (Same as 128K Coco mode)
512K AVP mode: $000000 - $7FEFF (Except ROM, I/O & CTRL)

I/O: XFF00 - XFFFF
XFF00 - XFF03 PIAO (Same as old Coco)
XFF10 - XFF1F RESERVED
XFF20 - XFF23 PIA1 (Same as old Coco)
XFF30 - XFF3F RESERVED
XFF40 - XFF5F SCS
XFF60 - XFF7F UNDECODED (Current peripherals)
XFF90 - XFF9F GIME CHIP CONTROL
XFFA0 - XFFAF MMU
XFFB0 - XFFBF COLOR PALETTE
XFFC0 - XFFDF SAM CONTROL REGISTERS
XFFE0 - XFFFF INTERRUPT VECTORS

It is possible for a device to respond to more than one address, but only those listed above should be used.
Following is a detailed breakout of the I/O section.

FF00 - FF03 PIA0

BIT 0 = KEYBOARD ROW 1 and right joystick button one
BIT 1 = KEYBOARD ROW 2 and left joystick button one
BIT 2 = KEYBOARD ROW 3 and right joystick button two
BIT 3 = KEYBOARD ROW 4 and left joystick button two
BIT 4 = KEYBOARD ROW 5
BIT 5 = KEYBOARD ROW 6
BIT 6 = KEYBOARD ROW 7
BIT 7 = JOYSTICK COMPARISON INPUT

BIT 0 = (0=IRQ to CPU disabled; 1=IRQ to CPU enabled)
BIT 1 = (0=IRQ occurs on falling edge of Horiz sync)  
       (1=IRQ occurs on rising edge of Horiz sync)
BIT 2 = Normally 1 (0 changes data dir reg to $FF00)
BIT 3 = LSB of the two analog MUX select lines
BIT 4 = ALWAYS 1
BIT 5 = ALWAYS 1
BIT 6 = NOT USED
BIT 7 = HORIZONTAL SYNC INTERRUPT FLAG

BIT 0 = KEYBOARD COLUMN 1
BIT 1 = KEYBOARD COLUMN 2
BIT 2 = KEYBOARD COLUMN 3
BIT 3 = KEYBOARD COLUMN 4
BIT 4 = KEYBOARD COLUMN 5
BIT 5 = KEYBOARD COLUMN 6
BIT 6 = KEYBOARD COLUMN 7
BIT 7 = KEYBOARD COLUMN 8

BIT 0 = (0=IRQ to CPU disabled; 1=IRQ to CPU enabled)
BIT 1 = (0=IRQ occurs on falling edge of Field sync)  
       (1=IRQ occurs on rising edge of Field sync)
BIT 2 = Normally 1 (0 changes data dir reg to $FF02)
BIT 3 = MSB of the two analog MUX select lines
BIT 4 = ALWAYS 1
BIT 5 = ALWAYS 1
BIT 6 = NOT USED
BIT 7 = FIELD SYNC INTERRUPT FLAG

FF20 - FF23 PIA1

BIT 0 = CASSETTE DATA INPUT
BIT 1 = RS-232 DATA OUTPUT
BIT 2 = 6 BIT D/A LSB
BIT 3 = 6 BIT D/A
BIT 4 = 6 BIT D/A
BIT 5 = 6 BIT D/A
BIT 6 = 6 BIT D/A
BIT 7 = 6 BIT D/A MSB
BIT 0 = (0=FIRQ to CPU disabled; 1=FIRQ to CPU enabled)
BIT 1 = (0=Set flag on falling edge of CD)
       (1=Set flag on rising edge of CD)
BIT 2 = NORMALLY 1; 0 Changes Data dir reg to $FF20
BIT 3 = CASSETTE MOTOR CONTROL: 0=OFF  1=ON
BIT 4 = ALWAYS 1
BIT 5 = ALWAYS 1
BIT 6 = NOT USED
BIT 7 = CD Interrupt flag

BIT 0 = RS-232 DATA INPUT
BIT 1 = SINGLE BIT SOUND OUTPUT
BIT 2 = NOT USED
BIT 3 = VDG CTRL OUTPUT CSS
BIT 4 = VDG CTRL OUTPUT GM0 & UPPER/LOWER CASE NOT
BIT 5 = VDG CTRL OUTPUT GM1 & INVERT
BIT 6 = VDG CTRL OUTPUT GM2
BIT 7 = VDG CTRL OUTPUT A NOT/G

BIT 0 = (0=FIRQ to CPU disabled; 1=FIRQ to CPU enabled)
BIT 1 = (0=Set flag on falling edge of CART)
       (1=Set flag on rising edge of CART)
BIT 2 = NORMALLY 1; 0 Changes Data dir reg to $FF20
BIT 3 = SIX BIT SOUND ENABLE
BIT 4 = ALWAYS 1
BIT 5 = ALWAYS 1
BIT 6 = NOT USED
BIT 7 = CARTRIDGE Interrupt flag

FF27
USED FOR POWER UP SYSTEM CONFIGURATION, BIT DEFS
ARE NOT AVAILABLE AT THIS TIME

FFDA
TURN OFF DOUBLE SPEED

FFDB
SET TO DOUBLE SPEED

FFDE
SET TO ROM MODE

FFDF
SET TO ALL RAM MODE

GIME CHIP CONTROL REGISTERS: FF90 - FF9F

BIT 7 - 1=Color Computer compatible mode
BIT 6 - 1=MMU enabled
BIT 5 - 1=Chip IRQ output enabled

BIT 4 - 1=Chip FIRQ output enabled
BIT 3 - 1=DRAM at XFEXXX is constant
BIT 2 - 1=Standard SCS
BIT 1 - ROM map control (see table below)
BIT 0 - ROM map control (see table below)

<table>
<thead>
<tr>
<th>BIT 1</th>
<th>BIT 0</th>

BIT 7 - NOT USED
BIT 6 - NOT USED
BIT 5 - Timer input select: 0=70us, 1=83us
BIT 4 - NOT USED
BIT 3 - NOT USED
BIT 2 - NOT USED
BIT 1 - NOT USED
BIT 0 - MMU Task Register Select (TR)

BIT 7 - NOT USED
BIT 6 - NOT USED
BIT 5 - Interrupt from Timer enabled
BIT 4 - Horizontal border IRQ enabled
BIT 3 - Vertical border IRQ enabled
BIT 2 - Serial data IRQ enabled
BIT 1 - Keyboard IRQ enabled
BIT 0 - Cartridge IRQ enabled

BIT 7 - NOT USED
BIT 6 - NOT USED
BIT 5 - Interrupt from Timer enabled
BIT 4 - Horizontal border FIRQ enabled
BIT 3 - Vertical border FIRQ enabled
BIT 2 - Serial data FIRQ enabled
BIT 1 - Keyboard FIRQ enabled
BIT 0 - Cartridge FIRQ enabled

**FF94** - TIMER MOST SIGNIFICANT BYTE
**FF95** - TIMER LEAST SIGNIFICANT BYTE

The above timer is a 16 bit interval timer, the count automatically begins when a value is stored in the MSB. The input clock is either 14 MHz or horizontal sync as selected by BIT 5 of FF91. As the count falls through zero, an interrupt is generated (if enabled), and the count is automatically reloaded.

**FF96** - Reserved for future use
**FF97** - Reserved for future use

BIT 7 - 0=alphanumeric, 1=bit plane graphics
BIT 6 - 1=individual attributes enabled in alpha
BIT 5 - 1=color set flip for old artifacting screens
**FF98**
BIT 4 - 1=Monochrome signal output (on composite)
BIT 3 - 1=50 Hz vertical sync

BIT 7 - NOT USED
BIT 6 - NOT USED
BIT 5 - MSB of RED border color

FF9A
BIT 4 - MSB of GREEN border color
BIT 3 - MSB of BLUE border color
BIT 2 - LSB of RED border color
BIT 1 - LSB of GREEN border color
BIT 0 - LSB of BLUE border color

FF9B
NOT USED

BIT 7 - NOT USED
BIT 6 - Vertical offset address Y18
BIT 5 - Vertical offset address Y17

FF9C
BIT 4 - Vertical offset address Y16
BIT 3 - Vertical scroll bit (alpha mode)
BIT 2 - Vertical scroll bit (alpha mode)
BIT 1 - Vertical scroll bit (alpha mode)
BIT 0 - Vertical scroll bit (alpha mode)
BIT 7 - Vertical offset address Y15
BIT 6 - Vertical offset address Y14
BIT 5 - Vertical offset address Y13

FF9D
BIT 4 - Vertical offset address Y12
BIT 3 - Vertical offset address Y11
BIT 2 - Vertical offset address Y10
BIT 1 - Vertical offset address Y9
BIT 0 - Vertical offset address Y8

BIT 7 - Vertical offset address Y7
BIT 6 - Vertical offset address Y6
BIT 5 - Vertical offset address Y5

FF9E
BIT 4 - Vertical offset address Y4
BIT 3 - Vertical offset address Y3
BIT 2 - Vertical offset address Y2
BIT 1 - Vertical offset address Y1
BIT 0 - Vertical offset address Y0

BIT 7 - Horizontal virtual enable (HVEN)
BIT 6 - Horizontal offset address
BIT 5 - Horizontal offset address

FF9F
BIT 4 - Horizontal offset address
BIT 3 - Horizontal offset address
BIT 2 - Horizontal offset address
BIT 1 - Horizontal offset address
BIT 0 - Horizontal offset address

NOTE: HVEN enables a horizontal screen width of 256 bytes regardless of the resolution or color mode bits selected. This will allow a "virtual" screen somewhat larger than the displayed screen. The user can move the "window" (the displayed screen) by means of the horizontal offset address bits. In character mode, the screen width is 128 characters regardless of attribute (or 54, if double wide is selected).
VIDEO RESOLUTION

The combination of HRES and CRES bits determine the resolution of the screen. Listed below are the resolutions which are supported. Any combinations not listed below may not be supported in future versions.

**ALPHANUMERIC**: (Bit 7 of FF98=0, Bit 7 of FF90=0)

<table>

<td>128</td>
<td>2</td>
<td>16</td>
</tr>
</tbody>
</table>

In addition to the above modes, the previous Coco modes are available. These result when Bit 7 of FF90 is set, the HRES and CRES bits have no effect on these modes. The number of required banks of ram listed above is a minimum requirement. Please note that in the 2 color modes there are 8 pixels per byte, in the 4 color modes there are 4 pixels per byte and in the 16 color modes there are 8 pixels per byte.
CHARACTER ATTRIBUTE MODES

Individual attribute mode:  (Bit 5 of FF96 = 1)

In this mode, each character on the screen has its own attribute byte, this byte immediately follows the character byte. This method allows for great flexibility but costs a little bit of extra memory.

</table>

Individual character attributes are not available if Bit 7 of FF90 = 1 (Coco compatible mode).
CHAPTER 6
COCO III SUMMARY

The Color computer III has turned out to be a fine machine, it contains many features that until now have only been available in the more expensive machines. 512K of memory, 640 by 200 high resolution graphics mode, 16 colors at a time on some screens, a choice of 64 different colors.... and the list goes on. I will admit that the Coco III is not the most powerful home computer available, but it is the best buy on the market today. You will not be able to find a computer anywhere that has all of the features of the color computer III and sells for $219 dollars.

Can you imagine COCO MAX running on a 512K machine, using the 320 by 192, 16 color graphics screen! How about a 512K graphics adventure! What about spreadsheets, word processors and other business programs! Level II 059 for the Coco III is amazing, it features a windowing environment that will make MAC owners envy you! The possibilities for this machine are endless.

There are a couple of hidden tricks within the Basic ROM that I would like to mention at this point. First, type WIDTH 40, then type CLS 100. Thank you T. Harris and T. Earls, they are the ones who wrote the new Basic commands. (If you type CLS 100 again, you will find that the names are gone). Now for one more thing to try. Turn off the computer, press and hold down the ALT and CTRL keys while turning it back on. Pictured from left to right are M. Hawkins, T. Harris and T. Earls. (Nice photo guys!)

Don't worry, code space was not wasted, not only was there enough space left over in the ROM for that picture, but probably a couple more as well. Hmm, I wonder if...
